

# CMake

Using Android Studio 2.2 and higher (<https://developer.android.google.cn/studio/index.html>), you can use the NDK and CMake (<https://cmake.org/>) to compile C and C++ code into a native library. Android Studio then packages your library into your APK using Gradle, the IDE's integrated build system (<https://developer.android.google.cn/studio/build/index.html>).

If you are new to using CMake with Android Studio, go to Add C and C++ Code to Your Project (<https://developer.android.google.cn/studio/projects/add-native-code.html>) to learn the basics of adding native sources to your project, creating a CMake build script, and adding your CMake project as a Gradle dependency. This page provides some additional information you can use to customize your CMake build.

## Using CMake variables in Gradle

Once you link Gradle to your CMake project (<https://developer.android.google.cn/studio/projects/add-native-code.html#link-gradle>), you can configure certain NDK-specific variables that change the way CMake builds your native libraries. To pass an argument to CMake from your module-level `build.gradle` file, use the following DSL:

```
android {  
    ...  
    defaultConfig {  
        ...  
        // This block is different from the one you use to link Gradle  
        // to your CMake build script.  
        externalNativeBuild {  
            cmake {
```

This site uses cookies to store your preferences for site-specific language and display options.

OK

```

// Use the following syntax when passing arguments to variables:
// arguments "-DVAR_NAME=ARGUMENT".
arguments "-DANDROID_ARM_NEON=TRUE",
// If you're passing multiple arguments to a variable, pass them together:
// arguments "-DVAR_NAME=ARG_1 ARG_2"
// The following line passes 'rtti' and 'exceptions' to 'ANDROID_CPP_FEATURES'.
    "-DANDROID_CPP_FEATURES=rtti exceptions"
}
}
}
}
buildTypes {...}

// Use this block to link Gradle to your CMake build script.
externalNativeBuild {
    cmake {...}
}
}

```

The following table describes some of the variables you can configure when using CMake with the NDK.

Variable name	Arguments	Description
<code>ANDROID_TOOLCHAIN</code>	<ul style="list-style-type: none"> <li><code>clang</code> (default)</li> <li><code>gcc</code> (deprecated)</li> </ul>	Specifies the compiler toolchain CMake
<code>ANDROID_PLATFORM</code>	For a complete list of platform names and corresponding Android system images, see Android NDK Native APIs ( <a href="https://developer.android.google.cn/ndk/guides/stable_apis.html">https://developer.android.google.cn/ndk/guides/stable_apis.html</a> ).	<p>Specifies the name of the target Android example, <code>android-18</code> specifies Android</p> <p>Instead of changing this flag directly, you can use the <code>minSdkVersion</code> property in the <code>defaultProductFlavors</code> blocks of your module's <code>build.gradle</code> file (<a href="https://developer.android.google.cn/studio/">https://developer.android.google.cn/studio/</a> level). This makes sure your library is us</p>

		<p>Android. The CMake toolchain then chooses the platform version for the ABI you're building based on the following logic:</p> <ol style="list-style-type: none"> <li>1. If there exists a platform version for the ABI higher than <code>minSdkVersion</code>, CMake uses that version.</li> <li>2. Otherwise, if there exists platform version <code>minSdkVersion</code> for the ABI, CMake uses those platform versions. This is a regression because a missing platform version in the previous version of the toolchain meant there were no changes to the native code in the previous available version.</li> <li>3. Otherwise, CMake uses the next available platform version higher than <code>minSdkVersion</code>.</li> </ol>
<code>ANDROID_STL</code>	<p>For a complete list of options, see Helper Runtimes (<a href="https://developer.android.google.cn/ndk/guides/cpp-support.html#hr">https://developer.android.google.cn/ndk/guides/cpp-support.html#hr</a>)</p> <p>By default, CMake uses <code>gnustl_static</code>.</p>	Specifies the STL CMake should use.
<code>ANDROID_PIE</code>	<ul style="list-style-type: none"> <li>• <code>ON</code> (default when <code>ANDROID_PLATFORM</code> = <code>android-16</code> and higher)</li> <li>• <code>OFF</code> (default when <code>ANDROID_PLATFORM</code> = <code>android-15</code> and lower)</li> </ul>	Specifies whether to use position-independent code (PIE). Android's dynamic linker supports PIE (API level 16) and higher.
<code>ANDROID_CPP_FEATURES</code>	<p>This variable is empty by default. However, the following are a few examples of arguments you can pass:</p> <ul style="list-style-type: none"> <li>• <code>rtti</code> (indicates that your code uses RTTI)</li> </ul>	Specifies certain C++ features CMake uses when compiling your native library, such as Floating-Point Math (FPU) and C++ exceptions.

	<ul style="list-style-type: none"> <li>• <code>exceptions</code> (indicates that your code uses C++ exceptions)</li> </ul>	
<code>ANDROID_ALLOW_UNDEFINED_SYMBOLS</code>	<ul style="list-style-type: none"> <li>• <code>TRUE</code></li> <li>• <code>FALSE</code> (default)</li> </ul>	Specifies whether to throw an undefined symbol error when CMake encounters an undefined reference in your native library. To disable these type of errors, set the variable to <code>TRUE</code> .
<code>ANDROID_ARM_MODE</code>	<ul style="list-style-type: none"> <li>• <code>arm</code></li> <li>• <code>thumb</code> (default)</li> </ul>	Specifies whether to generate ARM target code in <code>thumb</code> mode. In <code>thumb</code> mode, each instruction is 16-bit wide and linked with the STL libraries in the <code>lib</code> directory. Passing <code>arm</code> tells CMake to generate object files in 32-bit arm mode.
<code>ANDROID_ARM_NEON</code>	<ul style="list-style-type: none"> <li>• <code>TRUE</code></li> <li>• <code>FALSE</code> (default)</li> </ul>	Specifies whether CMake should build with NEON support.
<code>ANDROID_DISABLE_NO_EXECUTE</code>	<ul style="list-style-type: none"> <li>• <code>TRUE</code></li> <li>• <code>FALSE</code> (default)</li> </ul>	Specifies whether to enable NX bit (https://en.wikipedia.org/wiki/NX_bit) , or <code>WX</code> feature. To disable this feature, pass <code>TRUE</code> .
<code>ANDROID_DISABLE_RELRO</code>	<ul style="list-style-type: none"> <li>• <code>TRUE</code></li> <li>• <code>FALSE</code> (default)</li> </ul>	Specifies whether to enable read-only relocations.
<code>ANDROID_DISABLE_FORMAT_STRING_CHECKS</code>	<ul style="list-style-type: none"> <li>• <code>TRUE</code></li> <li>• <code>FALSE</code> (default)</li> </ul>	Specifies whether to compile your source code with string protection. When enabled, the compiler will error if a non-constant format string is used in a <code>printf</code> style function.

When debugging CMake build issues, it's helpful to know the specific build arguments that Android Studio uses when cross-compiling for Android.

Android Studio saves the build arguments it uses for executing a CMake build, in a `cmake_build_command.txt` file. For each Application Binary Interface (ABI) that your app targets, and each build type (<https://developer.android.google.cn/studio/build/build-variants.html>) for those ABIs (namely, *release* or *debug*), Android Studio generates a copy of the `cmake_build_command.txt` file for that specific configuration. Android Studio then places the files it generates in the following directories:

```
<project-root>/<module-root>/externalNativeBuild/cmake/<build-type>/<ABI>/
```

**Tip:** In Android Studio, you can quickly view these files by using the search keyboard shortcut (**shift+shift**) and entering `cmake_build_command.txt` in the input field.

The following snippet shows an example of the CMake arguments to build a debuggable release of the `hello-jni` (<https://github.com/googlesamples/android-ndk/tree/master/hello-jni>) sample targeting the `armeabi-v7a` architecture.

```
Executable : /usr/local/google/home/{$USER}/Android/Sdk/cmake/3.6.3155560/bin/cmake
arguments :
-H/usr/local/google/home/{$USER}/Dev/github-projects/googlesamples/android-ndk/hello-jni/app/src/main/cpp
-B/usr/local/google/home/{$USER}/Dev/github-projects/googlesamples/android-ndk/hello-jni/app/.externalNativeBuild/cmake
-GAndroid Gradle - Ninja
-DANDROID_ABI=armeabi-v7a
-DANDROID_NDK=/usr/local/google/home/{$USER}/Android/Sdk/ndk-bundle
-DCMAKE_LIBRARY_OUTPUT_DIRECTORY=/usr/local/google/home/{$USER}/Dev/github-projects/googlesamples/android-ndk/hello-jni
-DCMAKE_BUILD_TYPE=Debug
-DCMAKE_MAKE_PROGRAM=/usr/local/google/home/{$USER}/Android/Sdk/cmake/3.6.3155560/bin/ninja
-DCMAKE_TOOLCHAIN_FILE=/usr/local/google/home/{$USER}/Android/Sdk/ndk-bundle/build/cmake/android.toolchain.cmake
-DANDROID_NATIVE_API_LEVEL=23
-DANDROID_TOOLCHAIN=clang
jvmArgs :
```

## Build arguments

The following table highlights the key CMake build arguments for Android. These build arguments are not meant to be set by developers. Instead, the Android Plugin for Gradle (<https://developer.android.google.cn/studio/releases/gradle-plugin.html>) sets these arguments based on the `build.gradle` configuration in your project.

Build Arguments	Description
<code>-G &lt;build-system&gt;</code>	<p>Type of build files that CMake generates.</p> <p>For projects in Android Studio with native code, the <code>&lt;build-system&gt;</code> is set to <code>Android Gradle - Ninja</code>. This setting indicates that CMake uses the ninja build system (<a href="https://ninja-build.org/">https://ninja-build.org/</a>) to compile and link the C/C++ sources for your app. CMake also generates a <code>android_gradle_build.json</code> file which contains metadata for the Gradle plugin about the CMake build such as compiler flags and names of targets.</p> <p>This setting indicates that CMake uses Gradle (<a href="http://tools.android.com/tech-docs/new-build-system/user-guide">http://tools.android.com/tech-docs/new-build-system/user-guide</a>) together with the ninja (<a href="https://ninja-build.org/">https://ninja-build.org/</a>) build system to compile and link the C/C++ sources for your app. The ninja build system is the only generator that Studio supports.</p>
<code>-DANDROID_ABI &lt;abi&gt;</code>	<p>The target ABI.</p> <p>The NDK supports a set of ABIs, as described in <a href="https://developer.android.google.cn/ndk/guides/abis.html#sa">ABI Management</a> (<a href="https://developer.android.google.cn/ndk/guides/abis.html#sa">https://developer.android.google.cn/ndk/guides/abis.html#sa</a>). This option is similar to the <code>APP_ABI</code> variable that the <code>ndk-build</code> (<a href="https://developer.android.google.cn/ndk/guides/ndk-build.html">https://developer.android.google.cn/ndk/guides/ndk-build.html</a>) tool uses.</p> <p>By default, Gradle builds your native library into separate <code>.so</code> files for the ABIs that NDK supports, and then packages them all into your APK. If you want Gradle to build only for certain ABI configurations, follow the instructions in <a href="https://developer.android.google.cn/studio/projects/add-native-code.html#specify-abi">Add C and C++ Code to Your Project</a> (<a href="https://developer.android.google.cn/studio/projects/add-native-code.html#specify-abi">https://developer.android.google.cn/studio/projects/add-native-code.html#specify-abi</a>).</p> <p>If the target ABI is not specified, CMake defaults to using <code>armeabi-v7a</code>.</p>

	<ul style="list-style-type: none"> <li>• <b>armeabi</b>: ARMv5TE based CPU with software floating point operations.</li> <li>• <b>armeabi-v7a</b>: ARMv7 based devices with hardware FPU instructions (VFPv3_D16).</li> <li>• <b>armeabi-v7a with NEON</b>: Same as armeabi-v7a, but enables NEON floating point instructions. This is equivalent to setting <b>-DANDROID_ABI=armeabi-v7a</b> and <b>-DANDROID_ARM_NEON=ON</b>.</li> <li>• <b>arm64-v8a</b>: ARMv8 AArch64 instruction set.</li> <li>• <b>x86</b>: IA-32 instruction set.</li> <li>• <b>x86_64</b> - Instruction set for the x86-64 architecture.</li> </ul>
<b>-DANDROID_NDK</b> <path>	Absolute path to the root directory of the NDK installation on your host.
<b>-DCMAKE_LIBRARY_OUTPUT_DIRECTORY</b> <path>	Location on your host where CMake puts the <b>LIBRARY</b> target files when built.
<b>-DCMAKE_BUILD_TYPE</b> <type>	Similar to the build types for the ndk-build ( <a href="https://developer.android.google.cn/ndk/guides/ndk-build.html">https://developer.android.google.cn/ndk/guides/ndk-build.html</a> ) tool. The valid values are <b>Release</b> and <b>Debug</b> . To simplify debugging, CMake does not strip the release or debug version as part of the build. However, Gradle strips binaries when it packages them in the APK.
<b>-DCMAKE_MAKE_PROGRAM</b> <program-name>	Tool to launch the native build system. The Gradle plugin sets this value to the CMake <b>ninja</b> generator bundled with the Android SDK.
<b>-DCMAKE_TOOLCHAIN_FILE</b> <path>	Path to the <b>android.toolchain.cmake</b> file that CMake uses for cross-compiling for Android. Typically, this file is located in the <b>\$NDK/build/cmake/</b> directory, where <b>\$NDK</b> is the NDK installation directory on your host. For more information about the toolchain file, see Cross Compiling for Android ( <a href="https://cmake.org/cmake/help/v3.7/manual/cmake-toolchains.7.html#cross-compiling-for-android">https://cmake.org/cmake/help/v3.7/manual/cmake-toolchains.7.html#cross-compiling-for-android</a> ) .
<b>-DANDROID_NATIVE_API_LEVEL</b> <level>	Android API level that CMake compiles for.
<b>-DANDROID_TOOLCHAIN</b> <type>	The compiler toolchain that CMake uses. Defaults to <b>clang</b>

# YASM support in CMake

NDK r15 and higher provides CMake support for building assembly code written in YASM ([//yasm.tortall.net](http://yasm.tortall.net)) to run on x86 and x86-64 architectures.

YASM is an open-source assembler for x86 and x86-64 architectures, based on the NASM assembler.

You may find it useful to link assembly language programs or routines with C code in order to access C libraries or functions from your assembly code. You can also include short assembly routines in your compiled C code to take advantage of the better machine performance that assembly code affords.

To build assembly code with CMake, make the following changes in your project's `CMakeLists.txt`:

1. Call `enable_language` ([//cmake.org/cmake/help/latest/command/enable\\_language.html](http://cmake.org/cmake/help/latest/command/enable_language.html)) with the value set to `ASM_NASM`.
2. Depending on whether you are building a shared library or an executable binary, call `add_library` ([//cmake.org/cmake/help/latest/command/add\\_library.html](http://cmake.org/cmake/help/latest/command/add_library.html)) or `add_executable` ([//cmake.org/cmake/help/latest/command/add\\_executable.html](http://cmake.org/cmake/help/latest/command/add_executable.html)). In the arguments, pass in a list of source files consisting of the `.asm` files for the assembly program in YASM and the `.c` files for the associated C libraries or functions.

The following snippet shows how you might configure your `CMakeLists.txt` to build a YASM program as a shared library.

```
cmake_minimum_required(VERSION 3.6.0)

enable_language(ASM_NASM)

add_library(test-yasm SHARED jni/test-yasm.c jni/print_hello.asm)
```

For an example of how to build a YASM program as an executable, see the [yasm](#)

## Reporting problems

If you run into any issues that aren't due to the open source version of CMake, report them via the [android-ndk/ndk](https://github.com/android-ndk/ndk/issues) (<https://github.com/android-ndk/ndk/issues>) issue tracker on GitHub.
